

CRYSS White Paper — Placeholder Summary

CRYSS applies the mechanistic purification engine from NODES to real experimental data, fitting equilibrium partitioning behaviour across solvents, salt-formers, and composition space. Using a constrained optimiser, it derives the parameters that govern recovery, impurity depletion, and solvent burden, allowing each system to be ranked by $R_{\max}$ and purification potential. CRYSS then collapses these results into intuitive heat-map insight layers that reveal which systems are genuinely viable for optimization.
